

Within your local environment code is written to build a web application. Once built a local repository is then pushed globally for greater access

Deployment Sketch

GitHub acts as a global repo to which local changes are pushed into. GitHub acts as a middleman of access for your local repo and deployment of the web application

Your local environment

(consisting of:)
- a server
- code editor
- terminal

GitHub

See your changes on the web application

(consists of:)
- hosting the code on another machine and making it accessible to others

Deploy or Redeploy to Heroku

Heroku allows users to interact with their web applications live outside of our local machines. changes made to code locally are cause for redeployment of the web app.

Once the web app has been deployed you can see it live and view any changes made when redeployed.
